Question 1**25 marks**

A student wishes to determine the percentage of ammonia in a solution of household window cleaner by titrating a diluted solution of the window cleaner against hydrochloric acid. The student needs to standardise hydrochloric acid used before titrating it against the dilute ammonia solution. The following steps were used.

Step 1: Preparation of Primary Standard.

A 4.850 g sample of anhydrous sodium carbonate was dissolved and transferred into a 500.0 mL volumetric flask and made up to volume with distilled water.

- (a) Determine the concentration of the **standard** sodium carbonate solution.

(2 marks)

- (b) (i) Sodium carbonate is used as a primary standard as it has a relatively high molar mass. Explain why it is important for a primary standard to have a relatively high molar mass.

(1 mark)

- (ii) Give two additional reasons (excluding high molar mass and solubility) why sodium carbonate is a suitable compound to be used as a primary standard.

Reason 1

Reason 2

Step 2: Standardisation of the HCl solution.

An average titre volume of 14.9 (± 0.1) mL of the primary standard solution from Step 1 was used to neutralise a 20.00 (± 0.03) mL aliquot hydrochloric acid solution.

- (d) Calculate the percentage uncertainty of the 20.00 mL aliquot of hydrochloric acid solution.

- (e) Calculate the percentage uncertainty of the average titre volume. (1 mark)

(1 mark)

- (f) Calculate the standardized concentration of HCl and the absolute uncertainty associated with the determined concentration. (Note: Assume the % uncertainty from the primary standard is negligible in this case.)

(5 marks)

Question 1 continued**Step 3: Determination of the % ammonia in window cleaner.**

A 20.00 mL sample of window cleaner, with a mass of 20.90 g, was transferred into a 250.00 mL volumetric flask and made up to the mark with distilled water. The diluted window cleaner (ammonia solution) was then transferred to a 50.00 mL burette and titrated against 25.00 mL aliquots of the standardised hydrochloric acid solution from Step 2.

The following results were obtained:

	Volume of diluted ammonia solution (mL)			
	Rough	1	2	3
Initial volume (mL)	0.50	1.20	2.55	1.30
Final volume (mL)	37.55	37.15	38.50	37.20
Titre volume (mL)				

(Note: You do not need refer to uncertainties in part (g) and (h))

(g) Determine the average titre volume.

(1 mark)

(h) Determine the percentage of ammonia in the window cleaner solution.
(Note: if you were unable to determine the concentration of standardised HCl in part (e) on page 3, use $[\text{HCl}] = 0.100 \text{ mol L}^{-1}$)

(7 marks)

The titration curve of the reaction between the diluted ammonia solution and hydrochloric acid in Step 3 is shown below.

The student had 3 indicators to choose from for the titration in Step 3.

Indicator	pH range	Colour (lower pH – higher pH)
Methyl orange	3.1 – 4.4	red – yellow
Thymol blue	1.2 – 2.8	red – yellow
Phenolphthalein	8.3 – 10.0	colourless – pink

(g) Which indicator should they choose to identify the equivalence point?

(1 mark)

(f) Explain your choice of indicator, using appropriate chemical equations. Include the term 'equivalence point' and 'end point' in your response.

Question 2**14 marks**

Marble is composed mainly of calcium carbonate, CaCO_3 , with some impurities.

A 2.48 g sample of marble was dissolved in 500.0 mL of standardised 0.204 mol L^{-1} nitric acid. The mixture fizzed as carbon dioxide was produced and the marble completely dissolved. After the reaction mixture finished bubbling, samples of the remaining solution were transferred to a 50.00 mL burette and titrated against 20.00 mL aliquots of 0.100 mol L^{-1} NaOH solution. The average titre volume required was determined as 18.70 mL.

- (a) Calculate the percentage by mass of calcium carbonate in the sample of marble.

(9 marks)

- (b) State the effect of rinsing the following equipment with the solution given on the apparent % of calcium carbonate in the sample of marble.
Use "increase", "decrease" or "no change".

	Equipment	Rinsed with	Effect on apparent % of calcium carbonate in sample of marble
(i)	burette	distilled water	-
(ii)	pipette	distilled water	-
(iii)	conical flask	distilled water	-

(3 marks)

- (c) Explain your response to part (b) (i)
